The U.S. Department of Agriculture (USDA) prohibits discrimination in its programs on the basis of race, color, national origin, gender, religion, age, disability, marital or familial status, or political beliefs. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (braille, large print, audiotape, etc.) should contact the USDA Office of Communications at 202-720-5881 (voice) or 202-720-7808 (TDD).

To file a complaint, write the Secretary of Agriculture, USDA, Washington, DC 20250, or call 202-720-7327 (voice) or 202-720-1127 (TDD). USDA is an equal employment opportunity employer.

---

Mention of companies or commercial products in this report does not imply recommendation or endorsement by the U.S. Department of Agriculture over others not mentioned. USDA neither guarantees nor warrants the standard of any product mentioned. Product names are mentioned solely to report factually on available data and to provide specific information.

---

This publication reports research involving pesticides. All uses of pesticides must be registered by appropriate State and/or Federal agencies before they can be recommended.

---

**CAUTION:** Pesticides can be injurious to humans, domestic animals, desirable plants, and fish or other wildlife—if they are not handled or applied properly. Use all pesticides selectively and carefully. Follow recommended practices for the disposal of surplus pesticides and pesticide containers.

# **I. Purpose and Need for the Proposed Action**

## **A. Introduction**

The U.S. Department of Agriculture (USDA), Animal and Plant Health Inspection Service (APHIS), is proposing to cooperate with State organizations and cotton grower organizations in a program to eradicate the boll weevil in the State of Mississippi. The proposed program is a component of the National Boll Weevil Cooperative Control Program (national program), which has adopted an incremental strategy to eradicate the boll weevil from the U.S. Cotton Belt. In this site-specific environmental assessment (EA), APHIS analyzes the potential effects of the proposed program's alternatives (including no action) and considers characteristics and issues that may be special or unique to the State of Mississippi.

Since its introduction in southern Texas in the late 1800's, the boll weevil (*Anthonomus grandis* Boheman) has spread across the U.S. Cotton Belt. It annually causes economic losses to the agricultural industry and to consumers. Since the early 1950's, the nation's agricultural community has acknowledged the need for a beltwide strategy for controlling the boll weevil. Since the first pilot program in 1971, programs implemented in an incremental fashion have been successful in eradicating the boll weevil from over 3.5 million acres in major areas of the cotton belt.

In accordance with the National Environmental Policy Act of 1969 (NEPA) (42 U.S.C. 4321–4347 ) and its implementing regulations, APHIS and its cooperators analyzed the potential environmental effects of the national program to control the boll weevil in a programmatic document, the “National Boll Weevil Cooperative Control Program, Final Environmental Impact Statement—1991” (EIS). The EIS analyzed alternatives and control methods that could be used for boll weevil eradication and included detailed human health and nontarget species risk analyses. In the record of decision for the national program, APHIS committed to prepare site-specific EA's, tiered to the programmatic EIS, as necessary. This site-specific EA incorporates by reference all of the discussions, analyses, and conclusions of the EIS.

## **B. Purpose and Need**

APHIS is proposing to cooperate with other Federal and State agencies, grower groups, and growers in a program to eradicate the boll weevil from cotton fields in the State of Mississippi. The proposed action is needed to (1) reduce agricultural losses suffered by growers as a result of continuous boll weevil infestation, (2) substantially reduce the amount of pesticides used by growers and the cost of applying those pesticides to control boll weevil and other cotton pests, (3) maintain the biological integrity and efficacy of the national

program to eradicate the boll weevil, and (4) comply with relevant pest control statutes and regulations.

APHIS' authority for cooperation in this proposed program is based upon and complies with the Incipient and Emergency Control of Pests [Act] (1937), the Organic Act of the Department of Agriculture (1944), the Cooperation With State Agencies in the Administration and Enforcement of Certain Federal Laws Act (1962), and the Food Security Act of 1985.

Future funding for proposed boll weevil eradication programs such as this, which are components of a national incremental strategy to eradicate the boll weevil from the U.S. Cotton Belt, may be provided in part through loans from the USDA's Farm Service Agency (FSA). The FSA loan program, as proposed, would implement provisions of the "Agriculture, Rural Development, Food and Drug Administration, and Related Agencies Appropriates Act, 1997," which directed the Secretary of Agriculture to implement a new loan program to facilitate efforts to eradicate the boll weevil and to protect previous program areas from reinfestation. For proposed boll weevil eradication programs where there is a high probability that the grower organization may apply for a boll weevil eradication loan, FSA will serve as a cooperating agency for determining that no significant environmental impacts will exist. (FSA has no managerial role in boll weevil eradication programs, but functions solely in the approval, processing, and granting of loans to the programs' member organizations.)

## **II. Alternatives**

The national program to eradicate the boll weevil employs a beltwide integrated control strategy. Integrated control, in this case, involves the selection of a particular control method or combination of methods for an individual site, based on factors including variations in boll weevil biology, availability of overwintering sites, environmental concerns, weather patterns, and crop production requirements. Consistent with the strategy used in the national program, integrated control considered as alternatives within this EA include (1) limited no action, (2) biological control, (3) chemical control (azinphos-methyl, diflubenzuron, malathion, or methyl parathion), (4) cultural control (use of short-season cotton varieties and/or mandatory stalk destruction), (5) mechanical control (mass trapping and bait tubes), and (6) sterile insect technique.

## **A. Limited No Action**

For the purposes of this proposed program, the limited no action alternative is defined as no cooperative control action in an individual site within the program's area of operation.<sup>1</sup> It is conceivable that, because of a site's special characteristics, no control actions of any kind would be implemented. For example, measures that are agreed upon for the protection of endangered and threatened species could involve the enforcement of "no action" buffer zones. For the program to be effective in such areas, it would have to employ indirect methods such as mass trapping, the release of sterile boll weevils (when the technology is perfected and approved) in adjacent surrounding areas, or other methods which through attrition may eliminate the population of boll weevils from that site. The limited no action alternative affords the program a degree of flexibility to deal with extremely sensitive sites that may occur within a broad program area.

## **B. Biological Control**

Biological control (biocontrol) agents are predators, parasites, or microbial pathogens (viruses, bacteria, and fungi) that can be used to provide natural suppression of some insect species that damage agricultural crops. APHIS has reviewed research done on various biological control agents, including Naturalis-L and the parasitic wasp *Catolaccus grandis*. Constraints associated with the use of biological control agents for boll weevil control include the lack of artificial diets, mass propagation systems, or release systems. APHIS will continue to review, consider, and support the use of new or improved biological control strategies for the control of the boll weevil and other insect pests.

## **C. Chemical Control**

Four pesticides have been analyzed for program treatments and are registered for this use by the U.S. Environmental Protection Agency (EPA): malathion, azinphos-methyl, diflubenzuron, or methyl parathion (refer to the EIS for detailed information). Three pesticides (chlorpyrifos, dichlorvos, and propoxur) may be used in traps. Application methods, timing, and frequencies may vary (table 1 summarizes application rates and methods).

---

<sup>1</sup> A variety of interpretations may exist for the no action alternative, including entirely (no program) or possibly no Federal involvement. However, the most probable result of implementing either of these other interpretations would be that the existing high pesticide use patterns would continue. Under those circumstances, the environmental effects of no action would be more severe than those that might be incurred in the implementation of the proposed action. In APHIS' judgment therefore, the public's interest is better served through analysis of a limited no action alternative.

**Table 1. Proposed Pesticides**

<b>Insecticide</b>	<b>Application Rate (lb. a.i./acre)</b>	<b>Application Method</b>	<b>Active Ingredient</b>
Malathion	0.88-1.17	ULV aerial and ground	O,O-dimethyl phosphorodithioate of dimethyl mercaptosuccinate
Azinphos-methyl	0.25	ULV aerial and ground	Phosphorodithioic acid, O,O-dimethyl S-[(4-oxo-1,2,3,-benzotriazin-3(4H)-yl) methyl ester
Diflubenzuron	0.125	ULV aerial and ground	N-[(4-chlorophenyl) amino]carbonyl]-2,6-difluorobenzamide
Methyl parathion	0.5	ULV aerial and ground (encapsulated)	Phosphorothioic acid, O,O-dimethyl O-(4-nitrophenyl) ester
Chlorpyrifos	NA <sup>1</sup>	Laminated insecticide strip in trap	O,O-Diethyl O-(3,5k,6-trichloro-2-pyridyl) phosphorothioate
Dichlorvos	NA	Laminated insecticide strip in trap	2,2-Dichlorovinyl dimethyl phosphate
Propoxur	NA	Laminated insecticide strip in trap	O-isopropoxyphenyl N-methylcarbamate

<sup>1</sup> NA = Not applicable.

## D. Cultural Control

Cultural control is the modification of the crop environment to make it less favorable for pest reproduction and survival. The principal cultural methods proposed for use in this program (and analyzed in the EIS) are use of “short-season” techniques (growing short-season cotton varieties and manipulating planting and harvesting dates) and mandatory stalk destruction (postharvest stalk destruction with prohibition against cultivation of perennial cotton).

## E. Mechanical Control

Mechanical control involves the mass trapping of boll weevils. The boll weevils are attracted to a trap or an “attracticide device” (e.g., BWACT—“boll weevil attract and control tube”) containing a species-specific sex attractant and aggregation pheromone (a chemical that motivates insect behavior or development).

## F. Sterile Insect Technique

Sterile insect technique (SIT) involves the rearing, sterilization, and release of sterile weevils into wild boll weevil populations. Field trials have shown variable results for this alternative, and program managers do not consider the technology to be ready for implementation at this time. APHIS will continue to investigate the potential of SIT for eradication of the boll weevil.

### **III. Environmental Impacts of Proposed Action and Alternatives**

#### **A. Anticipated Environmental Impacts**

The environmental impacts that may result from implementation of the proposed action and/or its alternatives are considered in this section. Because the principal environmental concern over this proposed program relates to its use of chemical pesticides, this EA, therefore, focuses on the potential effects of program chemical pesticides. The EA uses both quantitative methods (especially to determine risks associated with the use of program chemicals) and qualitative methods to predict risk.

##### **1. Limited No Action**

Implementation of the limited no action alternative would mean that no control method would be used near the most sensitive sites, such as hospitals, schools, or wildlife refuges. Although this may result in less environmental impact initially than if these adjacent areas were treated, the untreated areas could serve as refuges for the pest and result in the need for prolonged treatments on surrounding areas until the boll weevil population is eliminated from its refuge site. Considering the prevailing need to protect sensitive sites, the use of the limited no action alternative could have an overall beneficial effect on the environment. Conversely, the lack of such an alternative probably would jeopardize the completion of the program, thereby influencing growers to return to previous pesticide uses with associated adverse environmental impacts.

The net effect of use of the limited no action alternative on human health would be a reduced risk of exposure and effects from program pesticides (in the short term for the limited no action site and in the long term for the entire program area). The net effect on the physical environment (air, land, and water) would be a reduction of residues and contaminants from program pesticides (in the short term for the limited no action site and in the long term for the entire program area). The net effect on sensitive nontarget species (wildlife, livestock, and domestic animals and plants) would be a reduced risk of exposure and effects from program pesticides. The overall effect of use of the limited no action alternative, therefore, is regarded as positive.

##### **2. Biological Control**

No direct adverse effects would be associated with the use of biological control agents. An indirect adverse effect might result if the biological control agents were not effective and the program or growers had to resort to the use of chemical pesticides late in the season to control boll weevils. The net effect of successful use of biological control agents on human health would be a reduced risk of exposure and effects from program pesticides. The net effect on

the physical environment (air, land, and water) would be a reduction of residues and contaminants from program pesticides. The net effect on sensitive nontarget species (wildlife, livestock, and domestic animals and plants) would be a reduced risk of exposure and effects from program pesticides. The overall effect of the use of biological control agents, therefore, is regarded as positive.

### **3. Chemical Control**

This EA considers potential effects that may result from use of any of the four pesticides that are proposed for this program: malathion, azinphos-methyl, diflubenzuron, and methyl parathion. Description of the risks associated with pesticides in traps is presented in the section on mechanical control. Refer to the EIS for greater detail on the formulations and use patterns. The EA's risk assessment integrated hazard information (pesticides' toxicity and environmental fate) with exposure predictions to develop the risk characterization. Exposure to any chemical agent may be associated with some level of risk, assessed with a degree of uncertainty. The U.S. Environmental Protection Agency (EPA) classifications (40 CFR 162.10, July 8, 1985; EPA, 1986) are used to describe the relative toxicities of the pesticides discussed in this section.

#### **a. Human Health**

The EA relied on quantitative risk assessment, using potential exposure scenarios for each program chemical application. The EA also relied on qualitative risk assessment, considering factors that may influence exposure and risk and that cannot be related quantitatively to exposure, or that may be beyond the capacity of program managers to control.

##### **(1) Quantitative Assessment**

Human health risk is quantified by comparing predicted exposure to toxicity reference levels based upon intrinsic hazards as described in detail in the EIS (volume 1, appendix B, section B.4.). Those toxicity reference values were applied to expected exposures to quantify risk. The classifications of the program pesticides' acute human oral toxicities are as follows: slight for malathion, very slight to slight for diflubenzuron, and moderate to severe for azinphos-methyl and methyl parathion. Refer to the discussion in the EIS for a more thorough review of toxicities and hazards of the program pesticides. The scenarios analyzed quantitatively in the EIS (volume 1, appendix B, section B.3.) do not differ substantially from conditions in the proposed program and are applicable to the program. The scenarios include dermal, inhalation, and dietary exposures to the public, as well as occupational exposures.

The margin of safety was determined by dividing the toxicity reference level of the pesticide by the exposure level determined in the scenario. The potential risk to program workers and the general public are presented in the programmatic EIS (volume 1, appendix B, section B.4.). Comprehensive training of all workers assures that there will be adequate margins

of safety to prevent adverse effects for all likely exposure routes. Likewise, the margins of safety to the general public indicate minimal risk and adequate safety against adverse effects.

## **(2) Qualitative Assessment**

Qualitative risk assessment is used to analyze risks that cannot be quantified easily, especially those involving incomplete exposure information or unclear relationships between dose and response. Thorough discussions of qualitative risks are presented in the EIS. This EA qualitatively assesses the effects of program pesticide formulations' impurities and degradation products, the anticipated cumulative and synergistic effects, and the effects on sensitive groups.

Impurities and degradation products may occur in formulated products, result from improper storage, or result from use of chemicals after the expiration date for shelf life. Program quality control guidelines require proper storage conditions and sampling of the product to ensure that impurities and degradation products pose no significant hazard to workers or the general public.

Cumulative effects are those which result from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions. Cumulative effects from simultaneous exposure to program treatments and to growers' treatments of other crops in adjacent fields is possible, but highly unlikely. To avoid risks for applicators and workers, growers are likely to make other pesticide applications at times when program treatments are not being made. Appropriate communication with growers and residents in adjacent properties through the notification process would assure that most residents will be aware of the treatments, understand the meaning of the treatment flags, and adhere to the required reentry periods.

Synergistic impacts are those which occur when two or more chemicals combine to cause effects that are different or stronger than the sum of their individual effects. Both cumulative and synergistic effects are more likely for the program organophosphate pesticides (malathion, azinphos-methyl, and methyl parathion) than for diflubenzuron. Organophosphates may elicit synergistic or cumulative effects if acetylcholinesterase activity has not recovered from inhibition by a simultaneous or earlier chemical exposure. Although growers are unlikely to treat adjacent fields synchronously with the boll weevil treatments, the potential for synergism is considerable if such activity takes place. Synergism of diflubenzuron is possible for individuals who are smokers, but is unlikely to pose any risk to other groups in the population. Cumulative and synergistic effects of these compounds are considerably less likely if proper safety procedures and reentry periods are followed for program and grower treatments. Although exposure to trap chemicals could result in cumulative or synergistic effects, the small amounts used and the trappers' safety precautions preclude such exposure. Refer to the EIS for more information about synergism.

Certain groups may have increased risk due to location, disease state, or other biological characteristics. Those who live next to cotton fields are at greatest risk. Infants may be more sensitive than adults to the effects of exposure to program pesticides. Individuals on certain medicines may be at increased risk. Some individuals may be less tolerant to exposure to these compounds because of a diminished ability to recover from the effects induced by exposure to these chemicals. Proper notification and instruction about reentry precautions may reduce appreciably their risk.

Individuals with multiple chemical sensitivity (MCS) may be extremely sensitive to even very low levels of exposure to a variety of chemical agents. Because of the highly variable nature of this condition, it is not possible to quantitatively or qualitatively assess the effects to such people. The percentage of MCS in the general population is unknown, partly because there is no acceptance of a single set of criteria for the diagnosis of MCS. It is possible that some residents with MCS could be disproportionately affected by program pesticide treatments. However, because the program would tend to reduce pesticide use on cotton, the overall incidence of MCS from pesticide use on cotton probably would be reduced.

## **b. The Physical Environment**

The chemical pesticides proposed for use in the program have potential to affect the physical environment (air, land, and water). Concerns over the effects of program pesticides on the physical environment relate to air pollution (from off-site drift), soil pollution (from drift or misdirected applications), and water pollution (from runoff, drift, and misdirected applications).

Program pesticides are not expected to affect the air quality in the general (overall) sense. Localized off-site drift may occur, however, from program treatments. Any off-site drift would be expected to be minimal because the proposed program chemicals have very low vapor pressures and are essentially nonvolatile, and because other program precautions are taken (refer to table 2-1 of the EIS).

The potential for soil pollution also is expected to be minimal. Applications are rarely misdirected because of sophisticated guidance and control systems that the program uses (satellite tracking, global positioning systems, and onboard computer systems that track an aircraft's path and spray operations). Also, the program pesticides degrade rapidly and do not persist for great lengths of time in soil (volume 1, appendix B, section B.8. of the EIS).

There is some potential for runoff of program pesticides if rainfall occurs shortly after treatments. However, operating procedures and recommended mitigation measures (tables 2-1 and 2-2 of the EIS) serve to minimize the effects of program chemicals on water bodies and the public who could drink from or consume fish from those water bodies. Program applications are unlikely to result in greater risk than that caused by existing pest control practices.

The potential for chemicals to leach into groundwater is related to their properties: solubility, soil/dissolved partition coefficient ( $K_{oc}$ ), hydrolysis, and soil half-lives. Generally, substances that exhibit high solubility and low degradation rates have the greatest potential to migrate through soil layers and reach groundwater aquifers. Modeling data indicates percolation of program pesticide residues through even the more porous soils to be negligible. It is unlikely, therefore, that groundwater would be affected.

### **c. Nontarget Species**

Risk assessments were conducted to evaluate the potential effects of program pesticides on nontarget species (domestic animals, wildlife, and plants). Following methodology detailed in the EIS (volume 1, appendix B, sections B.5. to B.7.), the risk assessment integrated hazard assessment and exposure assessment to arrive at a characterization of risk. Estimations of exposures to program insecticides for routine and extreme exposure scenarios were compared to toxicity reference levels for representative nontarget species. Based upon this comparison, risks were characterized as low, moderate, or high.

Detailed results of the nontarget risk assessments may be found in tables 4-3 through 4-6 in the EIS, and these data are summarized here. Malathion poses little risk to most terrestrial organisms, but it can pose a high risk to fish, amphibians, and aquatic invertebrates. Potential drift concentrations of azinphos-methyl present little risk, but a direct spray may present moderate to high risk to terrestrial organisms. For aquatic species, azinphos-methyl presents a high risk to fish, amphibians, and aquatic invertebrates. Potential drift concentrations of methyl parathion may present a moderate risk to some terrestrial species, while a direct spray presents moderate to high risks. Also, methyl parathion poses moderate risk to aquatic invertebrates. Diflubenzuron presents little risk to terrestrial organisms but may pose moderate to high risk to aquatic invertebrates.

Although program applications of pesticides pose no direct risk to plant species, there may be some indirect risk to plants associated with adverse effects to pollinators. Pollinators include many species of insects, such as bees, ants, wasps, as well as bats and/or birds for certain plants. It is unlikely that the application of the pesticides used in the program would eliminate all pollinators for the length of time sufficient to prevent pollination, but pesticides could temporarily reduce the number of potential pollinators for a particular plant species. Honey bees are more important as crop pollinators and honey producers. As a precaution, prior to treatments with azinphos-methyl, malathion, or methyl parathion, program personnel will notify registered apiarists in or near the treatment area of the date and approximate time of the treatment application.

The Migratory Bird Treaty Act prohibits the taking of migratory birds without a permit. "Take" is to pursue, hunt, shoot, wound, kill, capture, or collect, or attempt to pursue, hunt, shoot, wound, kill, capture, or collect migratory birds. The proposed program would not involve intentional take of migratory birds; any take would be incidental.

#### **4. Cultural Control**

The use of cultural control methods (crop rotation, short-season varieties, and mandatory postharvest stalk destruction) are anticipated to have minimal impact to human health, the physical environment, and nontarget species.

Tractors and other agricultural implements used in mandatory stalk destruction pose some risk of injury to equipment operators or others working near the equipment. Use of machinery produces considerable dust and particulate matter which could contribute to respiratory problems or allergies, but program experience indicates that such effects have been minimal to nonexistent.

Mandatory stalk destruction can result in soil disruption (soil losses and erosion), but such effects would not exceed the effects associated with routine procedures that growers use during planting, tilling, and harvesting operations. Conversely, crop rotation tends to reduce erosion and replace soil nitrogen lost during cotton production.

The use of short-season varieties may have a beneficial influence on the physical environment in that there would be a longer dormant period during which the cotton crop is not in the field. Populations of wildlife (small mammals, reptiles, and insects) that inhabit ecological niches associated with cotton fields would not be adversely impacted by program cultural control practices to any greater extent than the effects of current practices (planting and mechanical harvesting).

#### **5. Mechanical Control**

The use of mechanical control methods (traps or attracticide devices) are anticipated to have minimal impact to human health, the physical environment, and nontarget species.

Impacts could arise from the use of vehicles to place and monitor traps. Because workers or the public would have little exposure to minuscule amounts of pesticides (chlorpyrifos, dichlorvos, or propoxur) used in the traps, this alternative presents minimal risk. The only identifiable impacts on the physical environment would be minor soil displacement from vehicular and foot traffic during placement and monitoring of traps, and small amounts of plastic that could be left in the environment from broken traps. Mechanical control would have a negligible effect on nontarget species, because other insect species are not attracted to the traps and the amount of pesticide associated with the traps is insufficient to affect larger livestock or wildlife that may encounter the traps.

#### **6. Sterile Insect Technique**

Although sterile insect technique was not considered ready for implementation, its use is anticipated to have minimal impact to human health, the physical environment, and nontarget species.

No direct adverse effects on human health have been associated with the use of sterile insect technique, except for possible injury in the use of vehicles or mechanical release equipment. Release of sterile boll weevils is not expected to adversely impact air, land, or water. The release of sterile boll weevils would not impact nontarget species, except to result in minimal feeding damage to plants in the family Malvaceae (e.g., cotton, *Hibiscus* sp.).

## **B. Unique or Special Concerns**

### **1. Site-specific Characteristics**

Unique or special concerns for the proposed program area included potential pesticide impact to wetlands, major water bodies, groundwater, and potential outbreaks of secondary pests (such as beet armyworm).

Surface waters are important to the State of Mississippi. The western border of the State is edged by the Mississippi River. The Tennessee River flows along the northeastern corner of Mississippi. There is a large waterway constructed southward from the Tennessee River to the Tombigbee River. Other noteworthy bodies of water are the Tallahatchie River, the Pearl River, the Yazoo River, the Pascagoula River, the Big Black River, and the Sunflower River. There are several areas of wetlands and other bodies of water that provide the habitat for endangered and threatened species. In addition, many areas are used for aquaculture such as catfish farming, crayfish farming, and baitfish farming. Catfish ponds cover about 95,000 acres, mostly in the Delta. Some of the river basins are in large cotton-growing areas. In particular, areas around the Sunflower River are known to have intense cotton production. Protection of these water resources is an important consideration for program managers. In general, wetlands or water bodies are avoided in program operations and are further protected by the program's routine operational procedures and mitigation measures (listed in the EIS, tables 2-1 and 2-2); recommendations for additional protective measures appear in the next section of this EA.

The protection of groundwater is also an important consideration. There are five major aquifers in Mississippi. About 80 percent of the freshwater withdrawals within the State are from groundwater sources. Modeling data indicate that the physical properties and program use of chemicals make it unlikely that detectable leaching to groundwater would occur.

In addition to consideration for freshwater resources, APHIS analyzed the potential of the program to affect coastal resources. In particular, the potential of program actions to increase nonpoint pollution from agricultural runoff was considered as it relates to the Coastal Zone Management Act of 1972 and Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 (16 U.S.C. 1455b). Cotton is generally not grown in the coastal zone of Mississippi. Implementation of the routine operational procedures and mitigation measures (listed in the EIS, tables 2-1 and 2-2) used to protect wetlands and water bodies from adverse effects results in negligible impacts from program activities to coastal resources in Mississippi.

Some concern was registered earlier regarding the potential of the program treatments to increase the severity of outbreaks of secondary pests such as beet armyworm (which also feeds on cotton). Entomologists have noted that malathion is not effective on beet armyworm and believe it may temporarily reduce beneficial insects that are a factor in controlling that pest. Evidence suggests that beet armyworm outbreaks are also related to climatological influences. However, these occasional outbreaks of secondary pests during eradication programs are generally of short duration, and growers have seen the virtual elimination of the need to treat for secondary pests in those States that have completed eradication programs (Virginia, North Carolina, South Carolina, Georgia, Florida, Arizona, and California).

Consistent with Executive Order No. 12898, "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," APHIS considered the potential for disproportionately high and adverse human health or environmental effects on any minority populations and low-income populations. No disproportionate effects on such populations are anticipated as a consequence of implementing the preferred action.

In general, direct impacts, indirect impacts, cumulative impacts, and synergistic effects were considered in detail in the EIS. The site-specific consideration of the conditions that exist in this program area revealed no evidence to suggest that the EIS' discussions and conclusions related to these impacts would not apply also to this program.

## **2. Endangered and Threatened Species**

The Endangered Species Act (ESA) and its implementing regulations require Federal agencies to consult with the U.S. Department of the Interior's Fish and Wildlife Service (FWS) and/or the U.S. Department of Commerce's National Marine Fisheries Service (NMFS) to ensure their actions are not likely to jeopardize the continued existence of endangered or threatened species or result in the destruction or adverse modification of critical habitat. Federal agencies must determine if their actions "may affect" an endangered or threatened species or its habitat; if that determination is positive, they must initiate consultation with the FWS and/or the NMFS. According to the regulations, the Federal agency need not initiate formal consultation if it obtains the concurrence of the FWS and/or the NMFS, through informal consultation, with its determination that the action "is not likely to adversely affect" the endangered or threatened species or its habitat.

APHIS is consulting with FWS regarding endangered and threatened species and will comply with all protection measures stipulated in that consultation and mutually agreed on with FWS.

## **C. Additional Protective Measures**

Comprehensive lists of routine operational procedures and mitigation measures that are followed in all areas of the National Cooperative Boll Weevil Control Program are provided in the EIS. Refer to the EIS (tables 2-1 and 2-2) for those procedures and measures which constitute the standard protective measures for this program. The following additional

protective measures, recommended for the Mississippi Boll Weevil Cooperative Eradication Program, may further reduce the potential for adverse environmental effects from that program.

### **Pesticide Applications**

1. Program personnel overseeing applications of organophosphate (malathion, azinphos-methyl, and methyl parathion) pesticides are required to wear protective clothing or remain inside a closed vehicle with recirculating air, depending on the circumstances of the application.
2. Unprotected workers will be advised of the respective reentry periods following treatment. If azinphos-methyl is used, unprotected workers will not reenter the fields for 24 hours; following a methyl parathion treatment, unprotected workers will not reenter the field for 48 hours.
3. Program personnel shall immediately cease spraying operations if unprotected members of the public are observed within 100 feet of a cotton field being sprayed with malathion, azinphos-methyl, or methyl parathion.
4. Aerial applications will not be made to sensitive areas (residences, public buildings, water bodies, hospitals, primary and secondary schools, day care centers, in-patient clinics, nursing homes, parks, churches); program treatments will be applied only to cotton fields.
5. Aerial applications will be made at a height of 5–12 feet above the cotton canopy, unless precluded by obstructions.
6. Program personnel will familiarize aerial applicators with applicable operational procedures, mitigation measures, and protection measures.
7. Before initiating operations, APHIS will obtain concurrence from the U.S. Department of the Interior's Fish and Wildlife Service on protection measures that are required for endangered and threatened species, or their critical habitats.
8. Program personnel will be present during all treatments near sensitive areas; they will use dye cards along field edges to detect off-site drift of pesticides.
9. The program will report any incident of pesticide poisoning to the Mississippi Department of Health; information about the validity and probable cause will be used to develop additional protective measures, as necessary.

### **Notification Procedures**

1. Program personnel will provide advance written or oral notification of the approximate times and dates of treatments to area residents who reside within ¼-mile of treatments and

who formally request (providing their name, address, and telephone number) special notification.

2. Program managers will publish public notices of the availability of the environmental assessment (EA) for this program in local newspapers; copies of the programmatic EIS and the EA will be provided to program offices and regional libraries.
3. Growers participating in the program will be notified of treatment dates so that they may provide timely and appropriate notice of treatments and protective measures to persons in their employ or residing on properties who could be exposed to chemical pesticides.
4. Residents who are listed on any State agriculture or health department registry for multiple chemical sensitivity will be notified in writing or by telephone of the time of any program treatments to be made within ¼-mile of their residence.
5. Before beginning treatment with malathion, azinphos-methyl, or methyl parathion, program personnel shall notify all registered apiarists in or near the treatment area of the date and the approximate time of treatment.

## **D. Summary of Environmental Impacts**

The principal concern of this assessment is the potential consequence of program use of pesticides. All of the pesticides that could be used in this program (azinphos-methyl, diflubenzuron, malathion, or methyl parathion) are acknowledged to present a degree of risk to humans, the physical environment, and nontarget species. (Impacts from the use of nonchemical alternatives were determined to be insignificant (even in the absence of protective measures or mitigation) and therefore are not considered in detail in this section.) The impacts from chemical pesticides may be direct, indirect, cumulative, or synergistic in nature. Such impacts may be incurred even if a nonchemical alternative is chosen, but fails for some reason, and a chemical alternative has to be employed. The impacts may overlap, may vary by site, and may be reduced substantially through the application of mitigation and protective measures.

Direct impacts that are likely to occur as a consequence of this program are believed to be considerably less than those that are possible if the program were not implemented. The principal reasons are that, in the absence of a program: (1) more toxic chemicals could be used, (2) higher application rates could be used, (3) treatments could continue without abatement for many years, and (4) there would be no requirements for special protective measures. Minimal risk was determined for indirect toxic, systemic, reproductive, or cancer effects. Risks of cumulative impacts to human beings (systemic, reproductive, and cancer risks) were found to be minimal. Synergistic effects are reduced substantially through program operating procedures, including the requirement of safety equipment and reentry periods following treatments.

## **IV. Listing of Agencies, Organizations, and Individuals Consulted**

### **Government Agencies**

Gary Cunningham, Coordinator  
National Boll Weevil Eradication Program  
Plant Protection and Quarantine  
Animal and Plant Health Inspection Service  
U.S. Department of Agriculture  
4700 River Road, Unit 138  
Riverdale, MD 20737-1236

Bill Grefenstette, Senior Operations Officer  
National Boll Weevil Eradication Program  
Plant Protection and Quarantine  
Animal and Plant Health Inspection Service  
U.S. Department of Agriculture  
4700 River Road, Unit 138  
Riverdale, MD 20737-1236

Anthony Brashear, Program Manager  
Southeast Boll Weevil Eradication Program  
Plant Protection and Quarantine  
Animal and Plant Health Inspection Service  
U.S. Department of Agriculture  
Bell Oaks Plaza, Suite B  
2424 East South Blvd.  
Montgomery, AL 36116-2506

Michael R. Hinton, Chief  
Funds Management/Direct Loans Branch  
Loan Making Division  
Farm Service Agency  
U.S. Department of Agriculture  
1400 Independence Avenue, Mail Stop 0522  
Washington, DC 20013

**Finding of No Significant Impact  
for  
Mississippi Boll Weevil Cooperative Eradication Program  
Environmental Assessment,  
May 1997**

The U.S. Department of Agriculture (USDA), Animal and Plant Health Inspection Service (APHIS), has prepared an environmental assessment (EA) for its participation in the National Boll Weevil Cooperative Control Program (boll weevil program) in the State of Mississippi. Because of the probability that the cooperating grower group may request a USDA Farm Service Agency (FSA) boll weevil eradication loan, FSA has cooperated with APHIS in the preparation of this EA. The EA, incorporated by reference into this document, is tiered to the "Final Environmental Impact Statement for the National Boll Weevil Cooperative Control Program—1991." The EA is available from:

*U.S. Department of Agriculture  
Animal and Plant Health Inspection Service  
Plant Protection and Quarantine  
Southeastern Regional Office  
3505 25th Avenue, Building 1  
Gulfport, MS 39501*

The EA considered the impacts of alternatives and specific control methods for boll weevil eradication. Alternatives considered include limited no action, biological control, chemical control, cultural control, mechanical control, and sterile insect technique. The proposed program is needed to (1) reduce agricultural losses caused by the boll weevil and allow local growers to remain economically competitive, (2) substantially reduce the amount of pesticides used by growers against the boll weevil and other pests, (3) maintain the biological integrity and efficacy of the national program to eradicate the boll weevil, and (4) comply with relevant pest control statutes and regulations.

APHIS is consulting with the U.S. Department of the Interior, Fish and Wildlife Service (FWS), with regard to the protection of endangered and threatened species or their critical habitats. APHIS will adhere to protective measures designed specifically for this program and mutually agreed upon with FWS.

I find that implementation of the proposed boll weevil eradication program in the State of Mississippi will not significantly impact the quality of the human environment.

I have considered and base my finding of no significant impact on quantitative and qualitative risk assessments of the proposed pesticides, review of the program's operational characteristics, and the site-specific aspects of the proposed program's area. In addition, I find that the environmental process undertaken for this program is entirely consistent with the principles of "environmental justice,"

as expressed in Executive Order No. 12898. Lastly, because I have not found evidence of significant environmental impact associated with this program, I further find that an environmental impact statement does not need to be prepared and the program may proceed.
